CIS 471/571 (Winter 2020): Introduction to Artificial Intelligence

Lecture 11: Reinforcement Learning (Part 2)

Thanh H. Nguyen

Source: http://ai.berkeley.edu/home.html

Reminder

- Project 3: Reinforcement Learning
 - Deadline: Feb 17th, 2020

- Homework 3: MDPs and Reinforcement Learning
 - Deadline: Feb 20, 2020

- Solution of homework 2:
 - Will be posted today (Feb 13, 2020)

Thanh H. Nguyen 2/13/20

Reinforcement Learning

- We still assume an MDP:
 - A set of states $s \in S$
 - A set of actions (per state) A
 - A model T(s,a,s')
 - A reward function R(s,a,s')
- Still looking for a policy $\pi(s)$

Big idea: Compute all averages over T using sample outcomes

The Story So Far: MDPs and RL

Known MDP: Offline Solution

Goal Technique

Compute V*, Q*, π * Value / policy iteration

Evaluate a fixed policy π Policy evaluation

Unknown MDP: Model-Based

Goal Technique

Compute V*, Q*, π * VI/PI on approx. MDP

Evaluate a fixed policy π PE on approx. MDP

Unknown MDP: Model-Free

Goal Technique

Compute V*, Q*, π * Q-learning

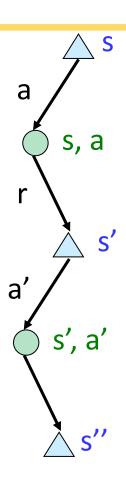

Evaluate a fixed policy π Value Learning

Model-Free Learning

- Model-free (temporal difference) learning
 - Experience world through episodes

$$(s, a, r, s', a', r', s'', a'', r'', s'''' \dots)$$

- Update estimates each transition (s, a, r, s')
- Over time, updates will mimic Bellman updates

Q-Learning

• We'd like to do Q-value updates to each Q-state:

$$Q_{k+1}(s,a) \leftarrow \sum_{s'} T(s,a,s') \left[R(s,a,s') + \gamma \max_{a'} Q_k(s',a') \right]$$

- But can't compute this update without knowing T, R
- Instead, compute average as we go
 - Receive a sample transition (s,a,r,s')
 - This sample suggests

$$Q(s, a) \approx r + \gamma \max_{a'} Q(s', a')$$

- But we want to average over results from (s,a) (Why?)
- So keep a running average

$$Q(s,a) \leftarrow (1-\alpha)Q(s,a) + (\alpha)\left[r + \gamma \max_{a'} Q(s',a')\right]$$

Example

- Two states: A, B
- Two actions: Up, Down
- Discount factor: $\gamma = 0.5$
- Learning rate: $\alpha = 0.5$
- Q(A, Down) = ?
- Q(B, Up) = ?

t	s_t	a_t	s_{t+1}	r_t
0	A	Down	В	2
1	В	Down	В	-4
2	В	Up	В	0
3	В	Up	A	3
4	A	Up	A	-1

$Q(s,a) \leftarrow (1-\alpha)Q(s,a) + (\alpha)$	$\left[r + \gamma \max_{a'} Q(s', a')\right]$
---	---

Q-Learning Properties

- Amazing result: Q-learning converges to optimal policy
 - -- even if you're acting suboptimally!

- Caveats:
 - You have to explore enough
 - You have to eventually make the learning rate small enough
 - ... but not decrease it too quickly
 - Basically, in the limit, it doesn't matter how you select actions
 (!)

Exploration vs. Exploitation

How to Explore?

- Several schemes for forcing exploration
 - •Simplest: random actions (ε-greedy)
 - Every time step, flip a coin
 - With (small) probability ε, act randomly
 - With (large) probability 1-ε, act on current policy
 - Problems with random actions?
 - You do eventually explore the space, but keep thrashing around once learning is done
 - One solution: lower ε over time
 - Another solution: exploration functions

Exploration Functions

- When to explore?
 - Random actions: explore a fixed amount
 - Better idea: explore areas whose badness is not (yet) established, eventually stop exploring
- Exploration function
 - Takes a value estimate **u** and a visit count **n**, and returns an optimistic utility, e.g.

$$f(u,n) = u + k/n$$

Regular Q-Update: $Q(s, a) \leftarrow_{\alpha} R(s, a, s') + \gamma \max_{a'} Q(s', a')$

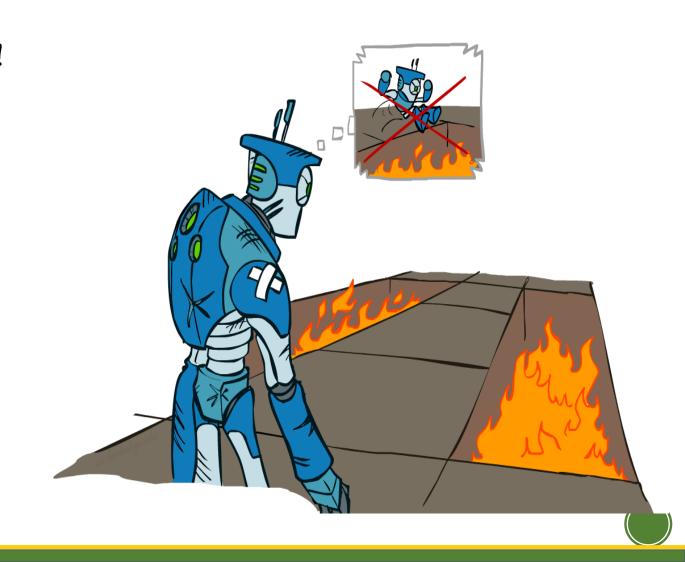

Modified Q-Update: $Q(s, a) \leftarrow_{\alpha} R(s, a, s') + \gamma \max_{a'} f(Q(s', a'), N(s', a'))$

Note: this propagates the "bonus" back to states that lead to unknown states as well!

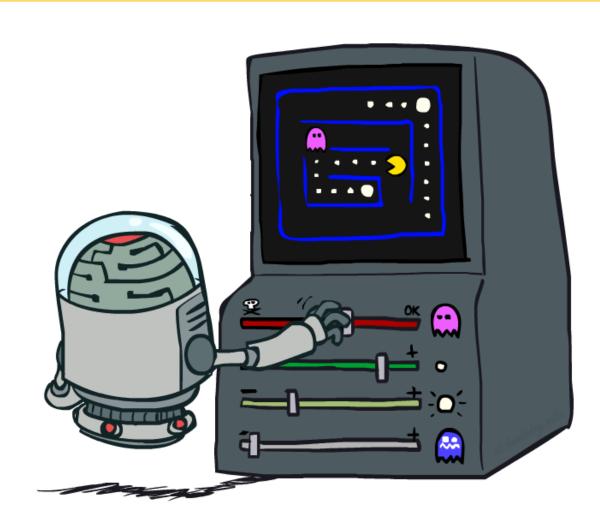

Regret

- Even if you learn the optimal policy, you still make mistakes along the way!
- Regret is a measure of your total mistake cost: the difference between your (expected) rewards, including youthful suboptimality, and optimal (expected) rewards
- Minimizing regret goes beyond learning to be optimal – it requires optimally learning to be optimal
- Example: random exploration and exploration functions both end up optimal, but random exploration has higher regret

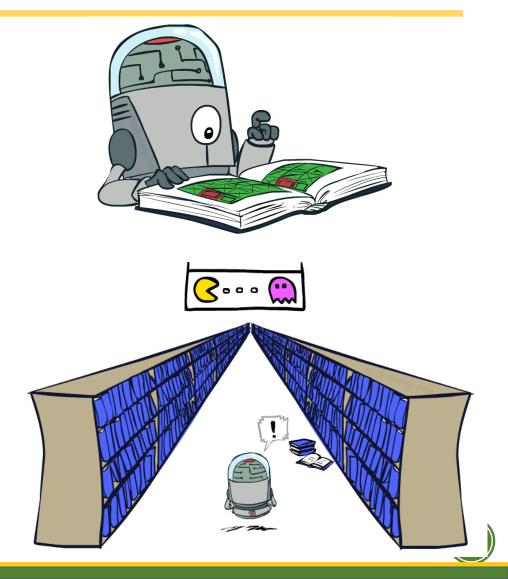

Approximate Q-Learning

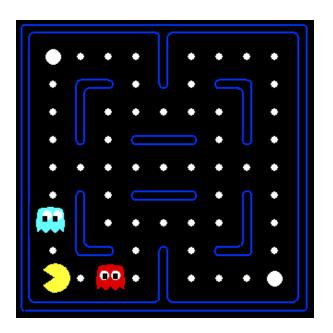

Generalizing Across States

- Basic Q-Learning keeps a table of all q-values
- In realistic situations, we cannot possibly learn about every single state!
 - Too many states to visit them all in training
 - Too many states to hold the q-tables in memory
- Instead, we want to generalize:
 - Learn about some small number of training states from experience
 - Generalize that experience to new, similar situations
 - This is a fundamental idea in machine learning, and we'll see it over and over again

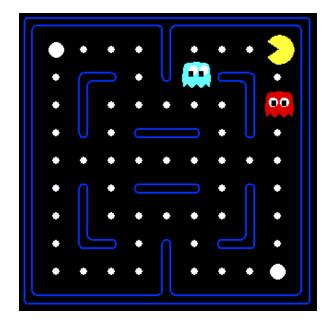

Example: Pacman

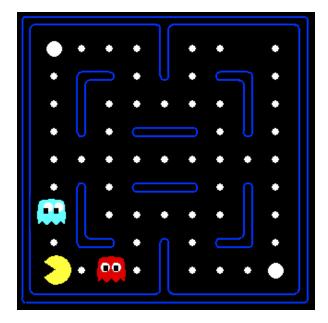

Let's say we discover through experience that this state is bad:

In naïve q-learning, we know nothing about this state:

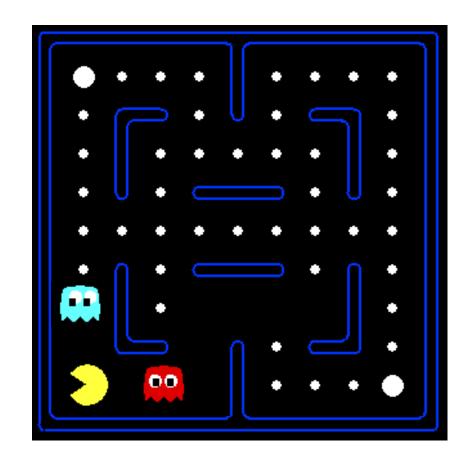

Or even this one!

Feature-Based Representations

- Solution: describe a state using a vector of features (properties)
 - Features are functions from states to real numbers (often 0/1) that capture important properties of the state
 - Example features:
 - Distance to closest ghost
 - Distance to closest dot
 - Number of ghosts
 - 1 / (dist to dot)²
 - Is Pacman in a tunnel? (0/1)
 - etc.
 - Is it the exact state on this slide?
 - Can also describe a q-state (s, a) with features (e.g. action moves closer to food)

Linear Value Functions

• Using a feature representation, we can write a q function (or value function) for any state using a few weights:

$$V(s) = w_1 f_1(s) + w_2 f_2(s) + \ldots + w_n f_n(s)$$

$$Q(s,a) = w_1 f_1(s,a) + w_2 f_2(s,a) + \dots + w_n f_n(s,a)$$

- Advantage: our experience is summed up in a few powerful numbers
- Disadvantage: states may share features but actually be very different in value!

Approximate Q-Learning

$$Q(s,a) = w_1 f_1(s,a) + w_2 f_2(s,a) + \dots + w_n f_n(s,a)$$

• Q-learning with linear Q-functions:

transition
$$= (s, a, r, s')$$

difference =
$$\left[r + \gamma \max_{a'} Q(s', a')\right] - Q(s, a)$$

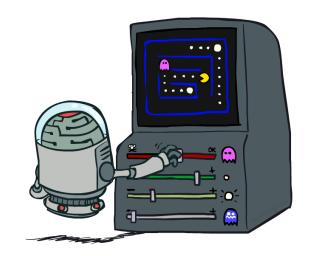

$$Q(s, a) \leftarrow Q(s, a) + \alpha$$
 [difference]

$$w_i \leftarrow w_i + \alpha$$
 [difference] $f_i(s, a)$

Approximate Q's

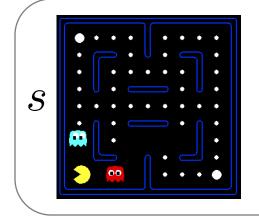

- Adjust weights of active features
- E.g., if something unexpectedly bad happens, blame the features that were on: disprefer all states with that state's features
- Formal justification: online least squares

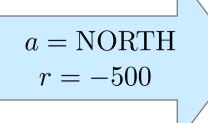

Example: Q-Pacman

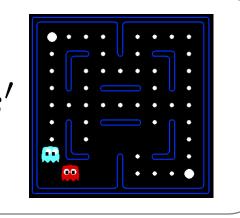

$$Q(s,a) = 4.0 f_{DOT}(s,a) - 1.0 f_{GST}(s,a)$$

 $f_{DOT}(s, NORTH) = 0.5$

 $f_{GST}(s, NORTH) = 1.0$

$$Q(s',\cdot)=0$$

$$Q(s, NORTH) = +1$$

 $r + \gamma \max_{a'} Q(s', a') = -500 + 0$

$$difference = -501$$

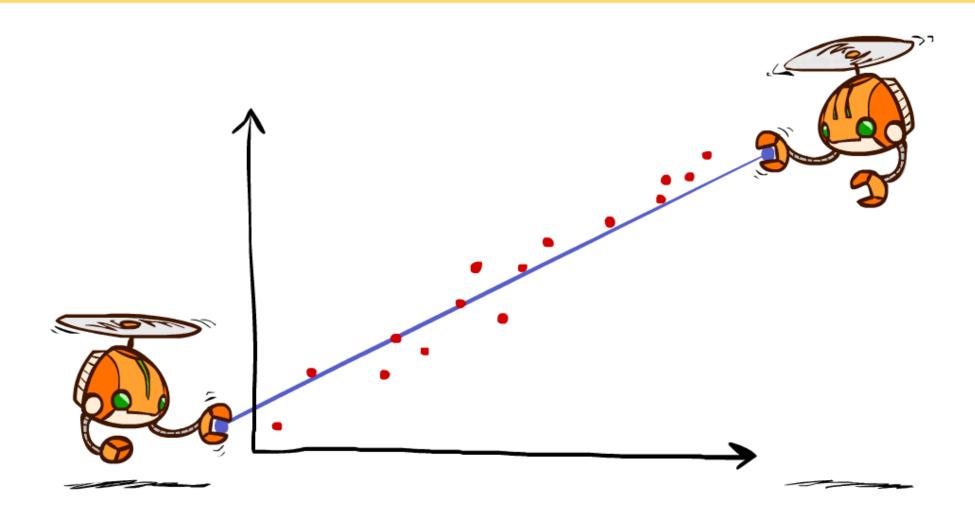

$$w_{DOT} \leftarrow 4.0 + \alpha [-501] 0.5$$

 $w_{GST} \leftarrow -1.0 + \alpha [-501] 1.0$

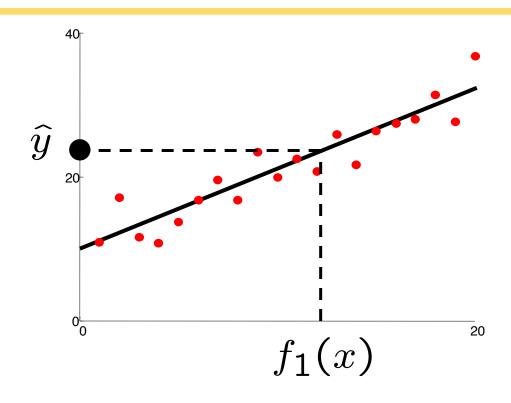

$$Q(s, a) = 3.0 f_{DOT}(s, a) - 3.0 f_{GST}(s, a)$$

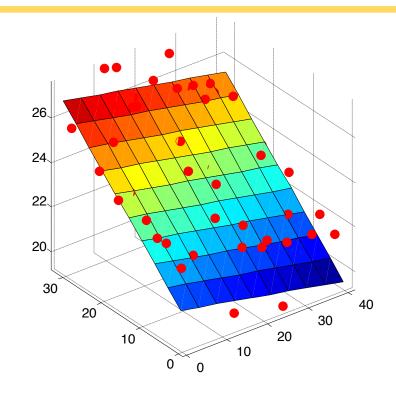

Q-Learning and Least Squares

Linear Approximation: Regression*

Prediction:

$$\hat{y} = w_0 + w_1 f_1(x)$$

Prediction:

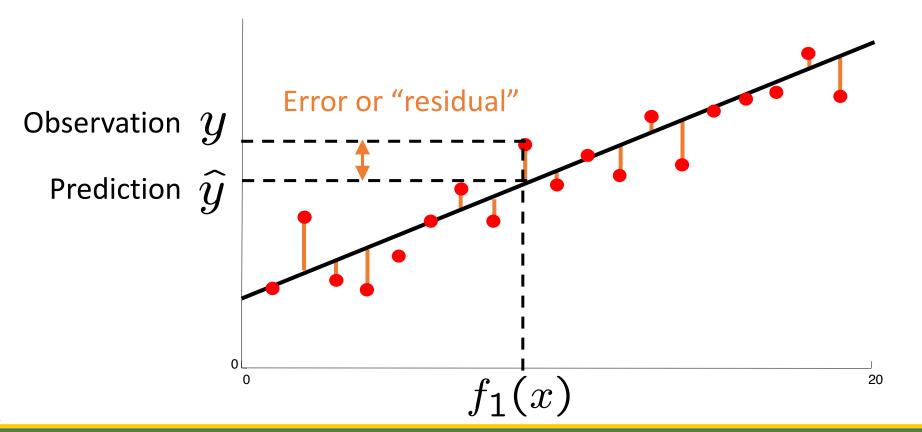

$$\hat{y}_i = w_0 + w_1 f_1(x) + w_2 f_2(x)$$

(21)

Thanh H. Nguyen

Optimization: Least Squares*

total error =
$$\sum_{i} (y_i - \hat{y_i})^2 = \sum_{i} \left(y_i - \sum_{k} w_k f_k(x_i)\right)^2$$

22

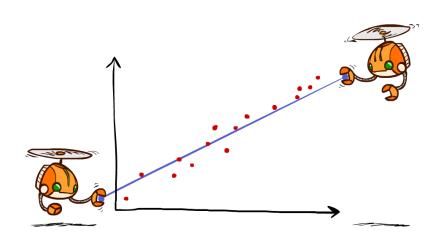

Minimizing Error*

Imagine we had only one point x, with features f(x), target value y, and weights w:

$$\operatorname{error}(w) = \frac{1}{2} \left(y - \sum_{k} w_{k} f_{k}(x) \right)^{2}$$

$$\frac{\partial \operatorname{error}(w)}{\partial w_{m}} = -\left(y - \sum_{k} w_{k} f_{k}(x) \right) f_{m}(x)$$

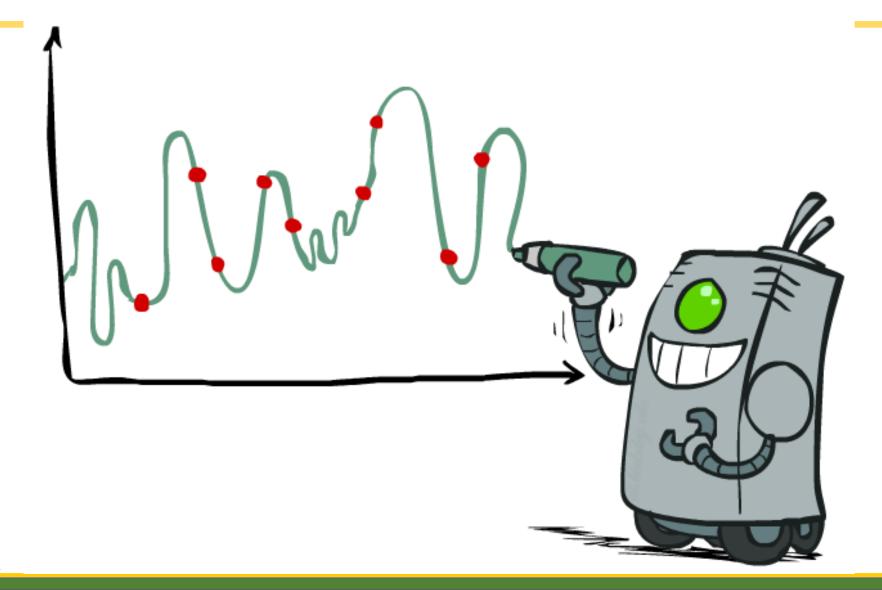

$$w_{m} \leftarrow w_{m} + \alpha \left(y - \sum_{k} w_{k} f_{k}(x) \right) f_{m}(x)$$

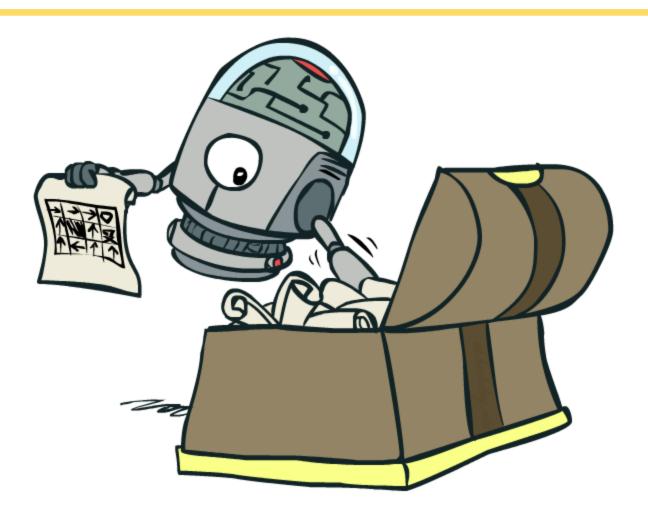

Approximate q update explained:

$$w_m \leftarrow w_m + \alpha \left[r + \gamma \max_a Q(s', a') - Q(s, a) \right] f_m(s, a)$$
"target" "prediction"

Overfitting: Why Limiting Capacity Can Help*

Policy Search

Thanh H. Nguyen

Policy Search

- Problem: often the feature-based policies that work well (win games, maximize utilities) aren't the ones that approximate V / Q best
 - E.g. your value functions from project 2 were probably horrible estimates of future rewards, but they still produced good decisions
 - Q-learning's priority: get Q-values close (modeling)
 - Action selection priority: get ordering of Q-values right (prediction)
 - We'll see this distinction between modeling and prediction again later in the course
- Solution: learn policies that maximize rewards, not the values that predict them

• Policy search: start with an ok solution (e.g. Q-learning) then fine-tune by hill climbing on feature weights

Policy Search

- Simplest policy search:
 - Start with an initial linear value function or Q-function
 - Nudge each feature weight up and down and see if your policy is better than before
- Problems:
 - How do we tell the policy got better?
 - Need to run many sample episodes!
 - If there are a lot of features, this can be impractical
- Better methods exploit lookahead structure, sample wisely, change multiple parameters...

Conclusion

- We're done with Part I: Search and Planning!
- We've seen how AI methods can solve problems in:
 - Search
 - Constraint Satisfaction Problems
 - Games
 - Markov Decision Problems
 - Reinforcement Learning
- Next up: Part II: Uncertainty and Learning!
